SIT330-770: Natural Language Processing

Week 8.1 - English Word Classes

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

- From the earliest linguistic traditions (Yaska and Panini 5th C. BCE, Aristotle 4th C. BCE), the idea that words can be classified into grammatical categories
 - part of speech, word classes, POS, POS tags
- 8 parts of speech attributed to Dionysius Thrax of Alexandria (c. 1st C. BCE):
 - noun, verb, pronoun, preposition, adverb, conjunction, participle, article
 - These categories are relevant for NLP today.

Two classes of words: Open vs. Closed

- Closed class words
 - Relatively fixed membership
 - Usually **function** words: short, frequent words with grammatical function
 - determiners: *a, an, the*
 - pronouns: *she, he, I*
 - prepositions: *on, under, over, near, by, ...*
- Open class words
 - Usually **content** words: Nouns, Verbs, Adjectives, Adverbs
 - Plus interjections: *oh, ouch, uh-huh, yes, hello*
 - New nouns and verbs like *iPhone* or *to fax*

Open class ("content") words

Nouns

Proper

Janet
Italy

Common

cat, cats
mango

Verbs

Main

eat
went

Auxiliary

can
had

Adjectives *old green tasty*

Adverbs *slowly yesterday*

Numbers

122,312
one

Interjections *Ow hello*

... more

Closed class ("function")

Determiners *the some*

Conjunctions *and or*

Pronouns *they its*

Prepositions *to with*

Particles *off up*

... more

- Assigning a part-of-speech to each word in a text.
- Words often have more than one POS.
- **book:**
 - VERB: (***Book** that flight*)
 - NOUN: (*Hand me that **book***).

"Universal Dependencies" Tagset

	Tag	Description	Example
Open Class	ADJ	Adjective: noun modifiers describing properties	<i>red, young, awesome</i>
	ADV	Adverb: verb modifiers of time, place, manner	<i>very, slowly, home, yesterday</i>
	NOUN	words for persons, places, things, etc.	<i>algorithm, cat, mango, beauty</i>
	VERB	words for actions and processes	<i>draw, provide, go</i>
	PROPN	Proper noun: name of a person, organization, place, etc..	<i>Regina, IBM, Colorado</i>
	INTJ	Interjection: exclamation, greeting, yes/no response, etc.	<i>oh, um, yes, hello</i>
Closed Class Words	ADP	Adposition (Preposition/Postposition): marks a noun's spacial, temporal, or other relation	<i>in, on, by under</i>
	AUX	Auxiliary: helping verb marking tense, aspect, mood, etc.,	<i>can, may, should, are</i>
	CCONJ	Coordinating Conjunction: joins two phrases/clauses	<i>and, or, but</i>
	DET	Determiner: marks noun phrase properties	<i>a, an, the, this</i>
	NUM	Numeral	<i>one, two, first, second</i>
	PART	Particle: a preposition-like form used together with a verb	<i>up, down, on, off, in, out, at, by</i>
	PRON	Pronoun: a shorthand for referring to an entity or event	<i>she, who, I, others</i>
	SCONJ	Subordinating Conjunction: joins a main clause with a subordinate clause such as a sentential complement	<i>that, which</i>
Other	PUNCT	Punctuation	<i>; , ()</i>
	SYM	Symbols like \$ or emoji	<i>\$, %</i>
	X	Other	<i>asdf, qwfg</i>

- There/**PRO** were/**VERB** 70/**NUM** children/**NOUN** there/**ADV** ./**PUNC**

SIT330-770: Natural Language Processing

Week 8.2 - Part of Speech Tagging

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

- Map from sequence x_1, \dots, x_n of words to y_1, \dots, y_n of POS tags

- Can be useful for other NLP tasks
 - Parsing: POS tagging can improve syntactic parsing
 - MT: reordering of adjectives and nouns (say from Spanish to English)
 - Sentiment or affective tasks: may want to distinguish adjectives or other POS
 - Text-to-speech (how do we pronounce “lead” or “object”?)
- Or linguistic or language-analytic computational tasks
 - Need to control for POS when studying linguistic change like creation of new words, or meaning shift
 - Or control for POS in measuring meaning similarity or difference

How difficult is POS tagging in English?

- Roughly 15% of word types are ambiguous
 - Hence 85% of word types are unambiguous
 - *Janet* is always PROP, *hesitantly* is always ADV
- But those 15% tend to be very common.
- So ~60% of word tokens are ambiguous
- E.g., *back*
 - earnings growth took a *back*/ADJ seat
 - a small building in the *back*/NOUN
 - a clear majority of senators *back*/VERB the bill
 - enable the country to buy *back*/PART debt
 - I was twenty-one *back*/ADV then

- How many tags are correct? (Tag accuracy)
 - About 97%
 - Hasn't changed in the last 10+ years
 - HMMs, CRFs, BERT perform similarly .
 - Human accuracy about the same
- But baseline is 92%!
 - Baseline is performance of stupidest possible method
 - "Most frequent class baseline" is an important baseline for many tasks
 - Tag every word with its most frequent tag
 - (and tag unknown words as nouns)
 - Partly easy because
 - Many words are unambiguous

Janet will back the bill

AUX/NOUN/VERB? NOUN/VERB?

- Prior probabilities of word/tag
 - "will" is usually an AUX
- Identity of neighboring words
 - "the" means the next word is probably not a verb
- Morphology and wordshape:
 - Prefixes unable: un- → ADJ
 - Suffixes importantly: -ly → ADV
 - Capitalization Janet: CAP → PROP

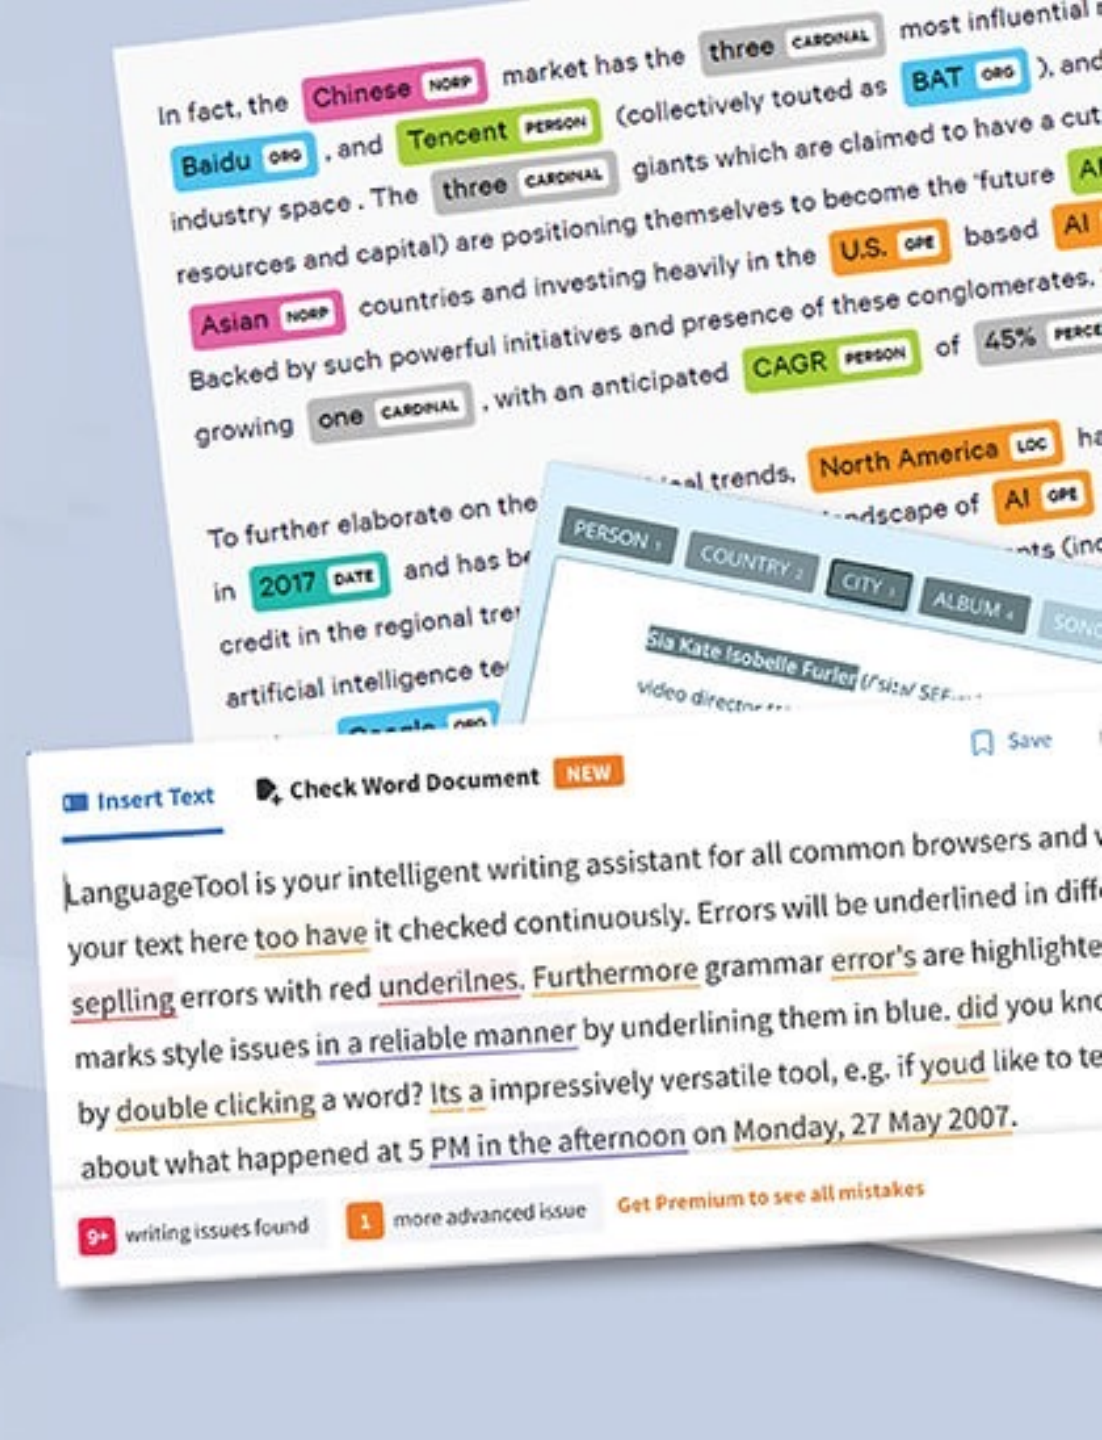

- Supervised Machine Learning Algorithms:
 - Hidden Markov Models
 - Conditional Random Fields (CRF)/ Maximum Entropy Markov Models (MEMM)
 - Neural sequence models (RNNs or Transformers)
 - Large Language Models (like BERT), finetuned
- All required a hand-labeled training set, all about equal performance (97% on English)
- All make use of information sources we discussed
 - Via human created features: HMMs and CRFs
 - Via representation learning: Neural LMs

SIT330-770: Natural Language Processing

Week 8.3 - Named Entity Recognition (NER)

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

- **Named entity**, in its core usage, means anything that can be referred to with a proper name. Most common 4 tags:
 - **PER** (Person): "Marie Curie"
 - **LOC** (Location): "New York City"
 - **ORG** (Organization): "Stanford University"
 - **GPE** (Geo-Political Entity): "Boulder, Colorado"
- Often multi-word phrases
- But the term is also extended to things that aren't entities:
 - dates, times, prices

- The task of named entity recognition (NER):
 - find spans of text that constitute proper names
 - tag the type of the entity.

Citing high fuel prices, [ORG **United Airlines**] said [TIME **Friday**] it has increased fares by [MONEY **\$6**] per round trip on flights to some cities also served by lower-cost carriers. [ORG **American Airlines**], a unit of [ORG **AMR Corp.**], immediately matched the move, spokesman [PER **Tim Wagner**] said. [ORG **United**], a unit of [ORG **UAL Corp.**], said the increase took effect [TIME **Thursday**] and applies to most routes where it competes against discount carriers, such as [LOC **Chicago**] to [LOC **Dallas**] and [LOC **Denver**] to [LOC **San Francisco**].

- Sentiment analysis: consumer's sentiment toward a particular company or person?
- Question Answering: answer questions about an entity?
- Information Extraction: Extracting facts about entities from text.

1) Segmentation

- In POS tagging, no segmentation problem since each word gets one tag.
- In NER we have to find and segment the entities!

2) Type ambiguity

[PER Washington] was born into slavery on the farm of James Burroughs.
[ORG Washington] went up 2 games to 1 in the four-game series.
Blair arrived in [LOC Washington] for what may well be his last state visit.
In June, [GPE Washington] passed a primary seatbelt law.

- How can we turn this structured problem into a sequence problem like POS tagging, with one label per word?
- [PER Jane Villanueva] of [ORG United] , a unit of [ORG United Airlines Holding] , said the fare applies to the [LOC Chicago] route.

- [PER Jane Villanueva] of [ORG United] , a unit of [ORG United Airlines Holding] , said the fare applies to the [LOC Chicago] route.

Words	BIO Label
Jane	B-PER
Villanueva	I-PER
of	O
United	B-ORG
Airlines	I-ORG
Holding	I-ORG
discussed	O
the	O
Chicago	B-LOC
route	O
.	O

Now we have one tag per token!!!

B: token that *begins* a span

I: tokens *inside* a span

O: tokens outside of any span

of tags (where n is #entity types):

1 O tag,

n B tags,

n I tags

total of $2n+1$

Words	BIO Label
Jane	B-PER
Villanueva	I-PER
of	O
United	B-ORG
Airlines	I-ORG
Holding	I-ORG
discussed	O
the	O
Chicago	B-LOC
route	O
.	O

- [PER Jane Villanueva] of [ORG United] , a unit of [ORG United Airlines Holding] , said the fare applies to the [LOC Chicago] route.

Words	IO Label	BIO Label	BIOES Label
Jane	I-PER	B-PER	B-PER
Villanueva	I-PER	I-PER	E-PER
of	O	O	O
United	I-ORG	B-ORG	B-ORG
Airlines	I-ORG	I-ORG	I-ORG

the	O	O	O
Chicago	I-LOC	B-LOC	S-LOC
route	O	O	O
•	O	O	O

- Supervised Machine Learning given a human-labeled training set of text annotated with tags
 - Hidden Markov Models
 - Conditional Random Fields (CRF)/ Maximum Entropy Markov Models (MEMM)
 - Neural sequence models (RNNs or Transformers)
 - Large Language Models (like BERT), finetuned

SIT330-770: Natural Language Processing

Week 8.4 – Hidden Markov Model (HMM) Part-of-Speech Tagging

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

- A Markov chain models the probabilities of state sequences, each drawn from a specific set.
- It assumes the future state depends only on the current state, not any prior ones.
- Markov chains are used to predict various phenomena
 - E.g., modeling weather patterns or word sequences.

Figure 8.8 A Markov chain for weather

$Q = q_1 q_2 \dots q_N$ a set of N **states**
 $A = a_{11} a_{12} \dots a_{N1} \dots a_{NN}$ a **transition probability matrix** A , each a_{ij} representing the probability of moving from state i to state j , s.t. $\sum_{j=1}^n a_{ij} = 1 \quad \forall i$
 $\pi = \pi_1, \pi_2, \dots, \pi_N$ an **initial probability distribution** over states. π_i is the probability that the Markov chain will start in state i . Some states j may have $\pi_j = 0$, meaning that they cannot be initial states. Also, $\sum_{i=1}^n \pi_i = 1$

Figure 8.8 A Markov chain for weather (a) and one for words (b), showing states and transitions. A start distribution π is required; setting $\pi = [0.1, 0.7, 0.2]$ for (a) would mean a probability 0.7 of starting in state 2 (cold), probability 0.1 of starting in state 1 (hot), etc.

- Markov Assumption:
 - Formally stated as: $P(q_i=a|q_1\dots q_{i-1}) = P(q_i=a|q_{i-1})$ implying that when predicting the future, only the present state matters

- A Markov chain computes probabilities for sequences of observable events.
- But often, the events of interest are hidden.
 - **Example:** Part-of-speech tags in text—hidden because we don't observe them directly.
- **Solution:** Hidden Markov Model (HMM) handles both observed and hidden events.
 - HMMs augment Markov chains

- A Hidden Markov Models (HMM) is a probabilistic sequence model that, given a sequence of units (words, letters, morphemes, sentences, etc.), computes a probability distribution over possible sequences of labels.
 - HMMs determine the likelihood of different label sequences and select the most probable sequence based on the observed data.
 - HMM is based on augmenting the **Markov chain**

- Input (O): Sequence of observations (o_1, o_2, \dots, o_T) drawn from vocabulary V .
- Assumptions of first-order HMM:
 - Markov Assumption:
 - Probability of state q_i depends only on the previous state (q_{i-1}).
 - $P(q_i | q_1 \dots q_{i-1}) = P(q_i | q_{i-1})$
 - Output Independence:
 - Probability of observation o_i depends only on the state that produced it q_i
 - $P(o_i | q_1 \dots q_i, \dots, q_T, o_1, \dots, o_i, \dots, o_T) = P(o_i | q_i)$

School of Information Technology,
Faculty of Sci Eng & Built Env

- An HMM tagger consists of two main components:
 - Matrix A which represents the tag transition.
 - Matrix B which represents emission probabilities.

- The A matrix encapsulates the tag transition probabilities, $P(t_i|t_{i-1})$, which express how likely a tag follows its predecessor.
 - Example:
 - The modal verb “**will**” commonly precedes the base form of a verb (VB), as in “**will race**”, leading to a high transition probability.
 - These probabilities are derived using maximum MLE by counting tag occurrences in a labeled corpus.
- Calculating Transition Probabilities:
 - In the WSJ corpus example, the modal verb tag (MD) is observed 13,124 times.
 - Out of these, MD transitions to a base verb (VB) 10,471 times.
 - Using MLE, we estimate $P(VB|MD) = C(MD, VB) / C(MD) = 10,471 / 13,124 \approx 0.80$.

- The B matrix contains emission probabilities, $P(w_i|t_i)$, which quantify the likelihood of a word being tagged with a specific tag.
- Emission Probability Calculation
 - To calculate emission probabilities, we count how often a word occurs with a particular tag in a corpus.
 - For instance, the MD tag associated with the word 'will' occurs 4,046 times in the WSJ corpus.
 - Hence, $P(\text{will}|\text{MD})$ is calculated as $C(\text{MD}, \text{will}) / C(\text{MD}) = 4,046 / 13,124 \approx 0.31$.

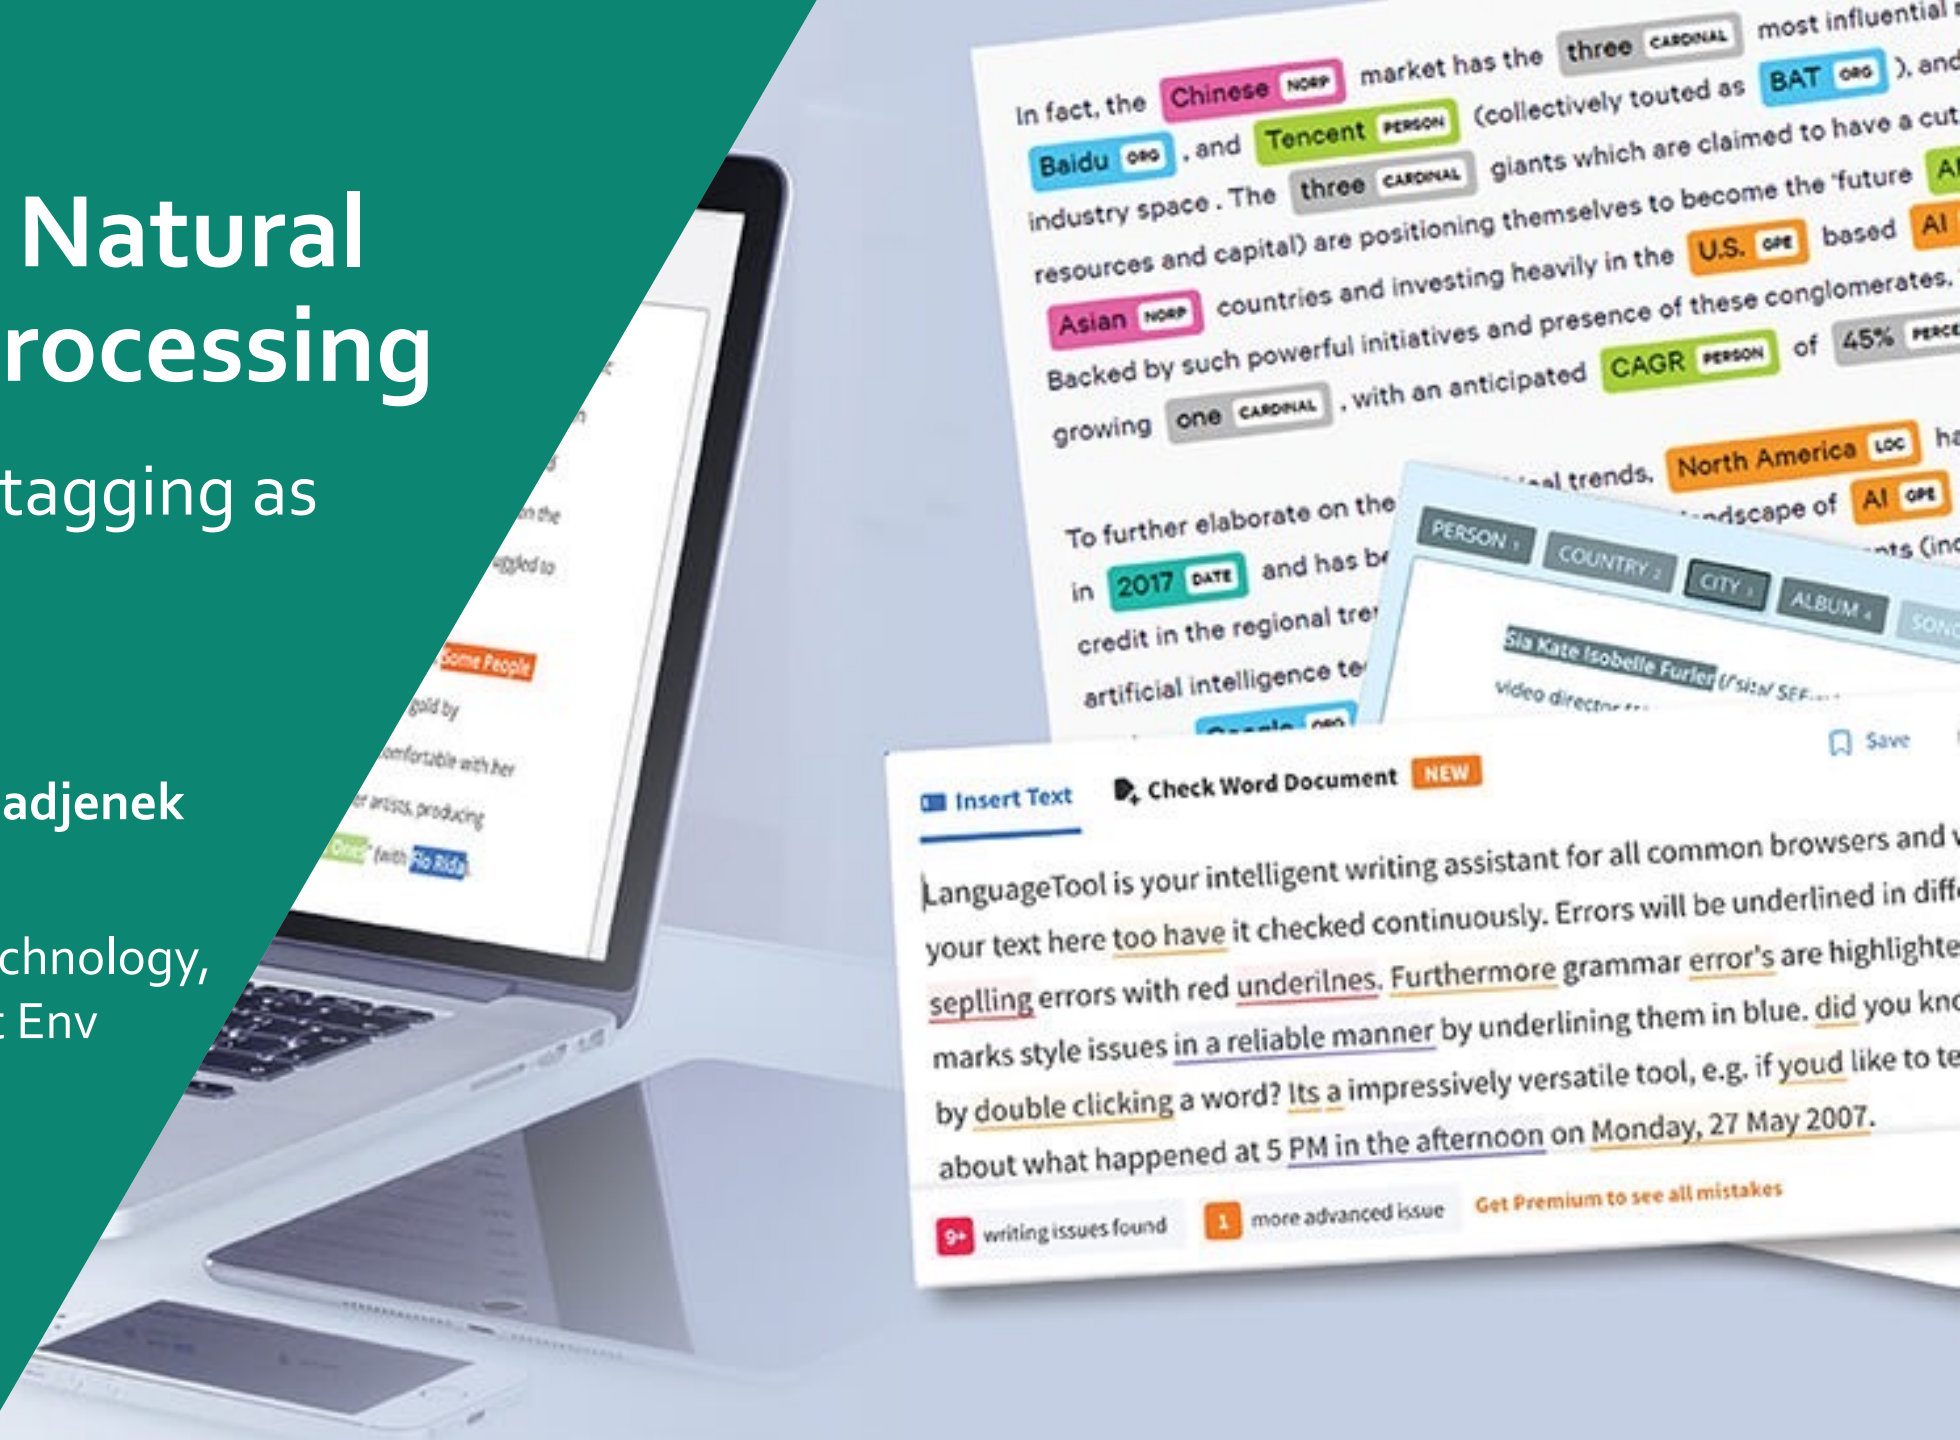

$Q = q_1 q_2 \dots q_N$	a set of N states
$A = a_{11} \dots a_{ij} \dots a_{NN}$	a transition probability matrix A , each a_{ij} representing the probability of moving from state i to state j , s.t. $\sum_{j=1}^N a_{ij} = 1 \quad \forall i$
$B = b_i(o_t)$	a sequence of observation likelihoods , also called emission probabilities , each expressing the probability of an observation o_t (drawn from a vocabulary $V = v_1, v_2, \dots, v_V$) being generated from a state q_i
$\pi = \pi_1, \pi_2, \dots, \pi_N$	an initial probability distribution over states. π_i is the probability that the Markov chain will start in state i . Some states j may have $\pi_j = 0$, meaning that they cannot be initial states. Also, $\sum_{i=1}^n \pi_i = 1$

SIT330-770: Natural Language Processing

Week 8.6 – HMM tagging as decoding

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

- Decoding is the process of determining the most probable sequence of hidden states (tags) based on observed data.
 - Given a sequence of observations $O = o_1, o_2, \dots, o_T$, decoding aims to find the most probable sequence of states $Q = q_1 q_2 \dots q_T$.
 - The input is an HMM $\lambda = (A, B)$, with **A** being the transition probabilities and **B** the emission probabilities.

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} P(t_1 \dots t_n | w_1 \dots w_n)$$

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} P(t_1 \dots t_n | w_1 \dots w_n)$$

MAP is “maximum a posteriori”
= most likely sequence

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} \frac{P(w_1 \dots w_n | t_1 \dots t_n) P(t_1 \dots t_n)}{P(w_1 \dots w_n)}$$

Bayes Rule

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} P(w_1 \dots w_n | t_1 \dots t_n) P(t_1 \dots t_n)$$

Dropping the
denominator

"Likelihood"

"Prior"

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} P(w_1 \dots w_n | t_1 \dots t_n) P(t_1 \dots t_n)$$

- HMM taggers make two further simplifying assumptions.
 - The probability of a word appearing depends only on its own tag and is independent of neighboring words and tags:

$$P(w_1 \dots w_n | t_1 \dots t_n) \approx \prod_{i=1}^n P(w_i | t_i)$$

- The second assumption, the bigram assumption, is that the probability of a tag is dependent only on the previous tag, rather than the entire tag sequence;

$$P(t_1 \dots t_n) \approx \prod_{i=1}^n P(t_i | t_{i-1})$$

- Plugging the simplifying assumptions results in the following equation for the most probable tag sequence from a bigram tagger:

$$\hat{t}_{1:n} = \operatorname{argmax}_{t_1 \dots t_n} P(t_1 \dots t_n | w_1 \dots w_n) \approx \operatorname{argmax}_{t_1 \dots t_n} \prod_{i=1}^n \overbrace{P(w_i | t_i)}^{\text{emission}} \overbrace{P(t_i | t_{i-1})}^{\text{transition}}$$

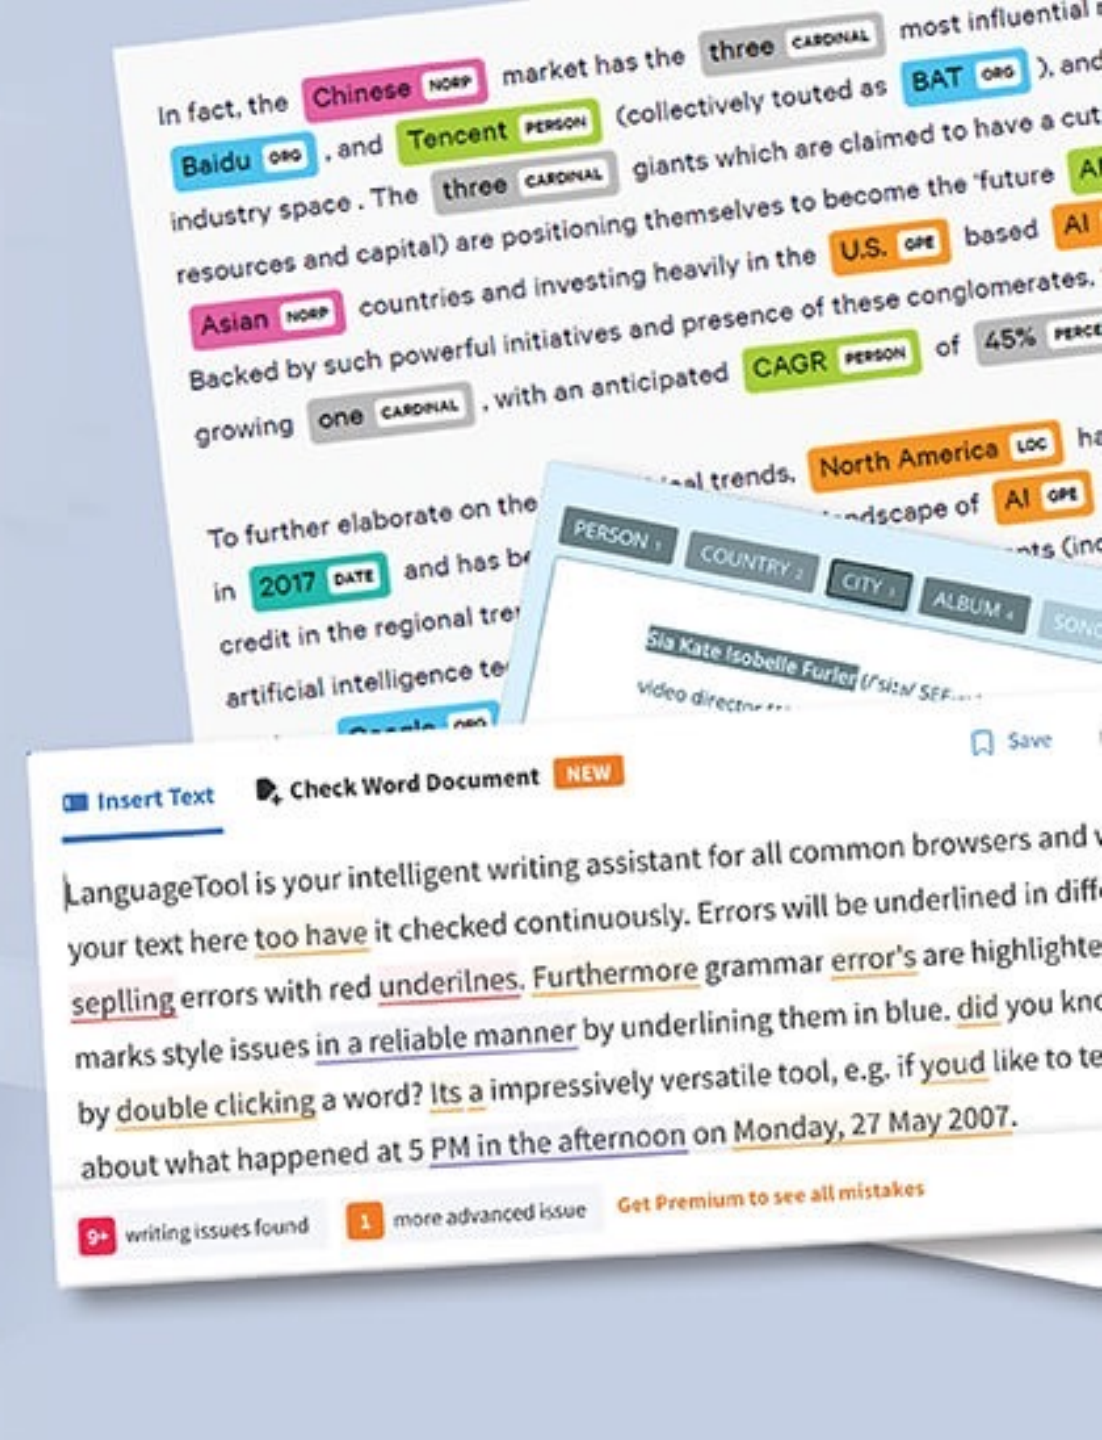

- The two parts correspond neatly to the **B** emission probability and **A** transition probability that we defined previously!

SIT330-770: Natural Language Processing

Week 8.7 – The Viterbi Algorithm

Dr. Mohamed Reda Bouadjenek

School of Information Technology,
Faculty of Sci Eng & Built Env

Computing the most probable sequence of tags

- A brute force approach to identify the most probable sequence of tags faces exponential complexity
 - This method is impractical for large datasets or real-time applications.
- **Solution:** The Viterbi algorithm **1967**
 - Leverages dynamic programming, streamlining the process by breaking the problem into manageable sub-problems
 - This approach significantly reduces computational demands and enhances processing speed, making it viable for complex tasks in real-world scenarios

Andrew Viterbi

The Viterbi Algorithm (i)

- The decoding algorithm for HMMs is the **Viterbi algorithm**
 - As an instance of **dynamic programming**, Viterbi resembles the dynamic programming minimum edit distance algorithm
- The Viterbi algorithm first sets up a probability matrix or lattice:
 - **Columns as observables** (words of a sentence in the same sequence as in sentence)
 - Rows as hidden states (all possible POS Tags are known)

tag the sentence
Janet will back the bill

The Viterbi Algorithm (ii)

- Each cell of the matrix is represented by $V_t(j)$ (Viterbi value for t: column, j: row) having the probability that the HMM is in **state j** (present POS Tag) after seeing the **first t observations** (past words for which matrix (cell) values has been calculated) and passing through the most **probable state sequence (previous POS Tag)** q_1, \dots, q_{t-1}
- Computed by recursively taking the most probable path that could lead us to this cell

$$v_t(j) = \max_{i=1}^N v_{t-1}(i) a_{ij} b_j(o_t)$$

$v_{t-1}(i)$	the previous Viterbi path probability from the previous time step
a_{ij}	the transition probability from previous state q_i to current state q_j
$b_j(o_t)$	the state observation likelihood of the observation symbol o_t given the current state j

The Viterbi Algorithm (iii)

- Each cell of the matrix is represented by $V_t(j)$ (Viterbi value for t : column, j : row) having the probability that the HMM is in **state j** (present POS Tag) after seeing the **first t observations** (past words for which matrix (cell) values has been calculated) and passing through the most **probable state sequence (previous POS Tag)** q_1, \dots, q_{t-1}

A sketch of the matrix for **Janet will back the bill**, showing the possible tags (q_i) for each word and highlighting the path corresponding to the correct tag sequence through the hidden states

States (parts of speech) which have a zero probability of generating a particular word according to the B matrix (such as the probability that a determiner DT will be realized as Janet) are greyed out

- Janet will back the bill → Janet/NNP will/MD back/VB the/DT bill/NN
