# Neural Networks and Deep Learning

#### Use cases for feedforward networks

Let's consider 2 (simplified) sample tasks:

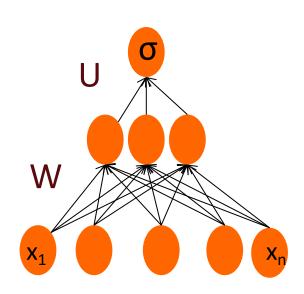

- Text classification
- 2. Language modeling

 State-of-the-art systems use more powerful neural architectures, but simple models are useful to consider!

# Classification: Sentiment Analysis

- We could do exactly what we did with logistic regression
- Input layer are binary features as before
- Output layer is o or 1

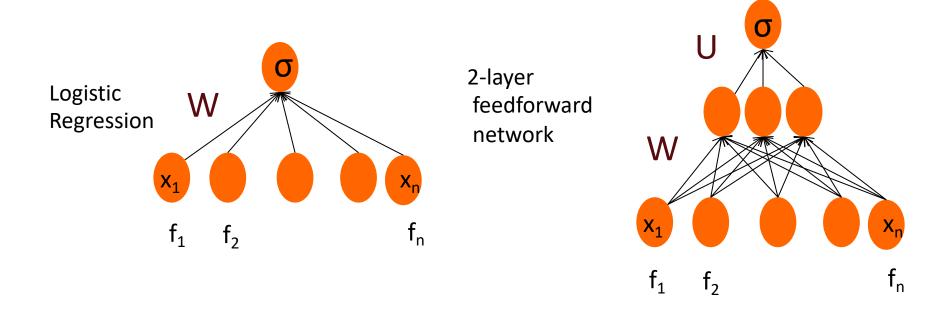

### Sentiment Features

Var	Definition
$\overline{x_1}$	$count(positive lexicon) \in doc)$
$x_2$	$count(negative lexicon) \in doc)$
<i>x</i> <sub>3</sub>	<pre> { 1 if "no" ∈ doc</pre>
$x_4$	$count(1st and 2nd pronouns \in doc)$
<i>x</i> <sub>5</sub>	$\begin{cases} 1 & \text{if "!"} \in \text{doc} \\ 0 & \text{otherwise} \end{cases}$
$x_6$	log(word count of doc)

### Feedforward nets for simple classification

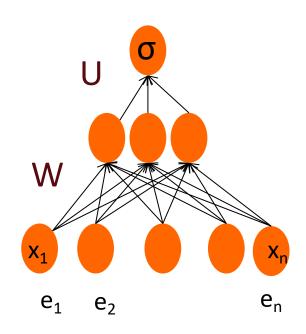

- Just adding a hidden layer to logistic regression
  - o allows the network to use non-linear interactions between features
  - which may (or may not) improve performance.

# Even better: representation learning

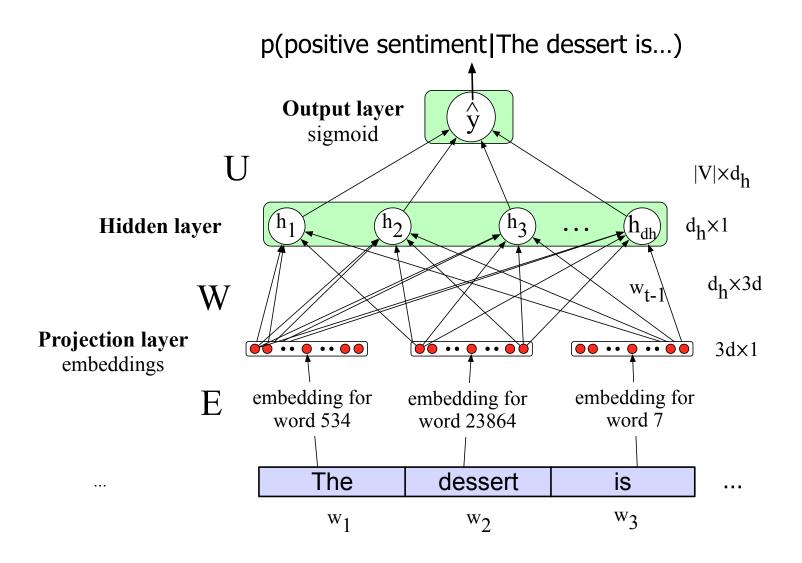

- The real power of deep learning comes from the ability to **learn** features from the data
- Instead of using hand-built human-engineered features for classification
- Use learned representations like embeddings!

# Neural Net Classification with embeddings as input features!

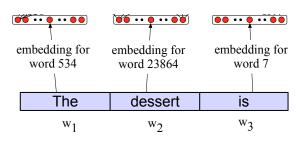

#### Issue: texts come in different sizes

- This assumes a fixed size length (3)!
- Kind of unrealistic.
- Some simple solutions (more sophisticated solutions later)
- 1. Make the input the length of the longest review
  - If shorter then pad with zero embeddings
  - Truncate if you get longer reviews at test time
- Create a single "sentence embedding" (the same dimensionality as a word) to represent all the words
  - Take the mean of all the word embeddings
  - Take the element-wise max of all the word embeddings
    - For each dimension, pick the max value from all words

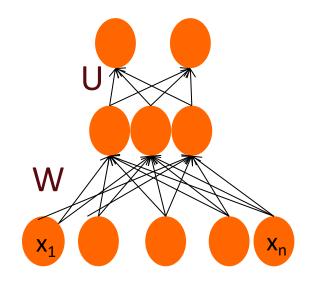

# Reminder: Multiclass Outputs

- What if you have more than two output classes?
  - Add more output units (one for each class)
  - And use a "softmax layer"

$$softmax(z_i) = \frac{e^{z_i}}{\sum_{j=1}^k e^{z_j}} \quad 1 \le i \le D$$

# Neural Language Models (LMs)

- Language Modeling: Calculating the probability of the next word in a sequence given some history.
  - We've seen N-gram based LMs
  - But neural network LMs far outperform n-gram language models
- State-of-the-art neural LMs are based on more powerful neural network technology like Transformers
- But simple feedforward LMs can do almost as well!

# Simple feedforward Neural Language Models

**Task**: predict next word  $w_t$ 

given prior words  $w_{t-1}$ ,  $w_{t-2}$ ,  $w_{t-3}$ , ...

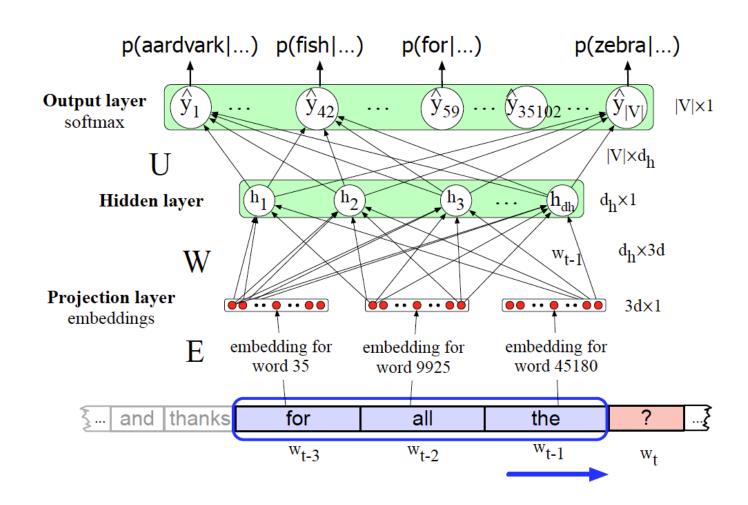

**Problem**: Now we're dealing with sequences of arbitrary length.

**Solution**: Sliding windows (of fixed length)

$$P(w_t|w_1^{t-1}) \approx P(w_t|w_{t-N+1}^{t-1})$$

# Neural Language Model

# Why Neural LMs work better than N-gram LMs

# Training data:

We've seen: I have to make sure that the cat gets fed.

Never seen: dog gets fed

#### Test data:

- I forgot to make sure that the dog gets \_\_\_\_\_
- N-gram LM can't predict "fed"!
- Neural LM can use similarity of "cat" and "dog" embeddings to generalize and predict "fed" after dog
