

What is a Language Model?

A model to assign a probability to a sentence

Machine Translation:

P(high winds tonight) > P(large winds tonight)

Spell Correction

The office is about iffeen minuets from my housel

P(about fifteen minutes from) > P(about fifteen minuets from)

Speech Recognition

P(I saw a van) >> P(eyes awe of an)

+ Summarization, question, answering, etc., etc.!!

1

Goal: compute the probability of a sentence or sequence of words:

 P(W) = P(w\_1, w\_2, w\_3, w\_4, w\_5...w\_6)

 Related task: probability of an upcoming word:
 P(w\_5 | w\_2, w\_2, w\_3, w\_4)

 A model that computes either of these:

 P(W) or P(w\_6 | w\_2, w\_2, ...w\_6.1) is called a language model.

 Better: the grammar But language model or LM is standard

4

How to compute P(W)

 How to compute this joint probability:
 P(its, water, is, so, transparent, that)

 Intuition: let's rely on the Chain Rule of Probability

Reminder: The Chain Rule

• Recall the definition of conditional probabilities

p(B|A) = P(A,B)/P(A) Rewriting: P(A,B) = P(A)P(B|A)

• More variables:

P(A,B,C,D) = P(A)P(B|A)P(C|A,B)P(D|A,B,C)

• The Chain Rule in General

P(x<sub>1</sub>,x<sub>2</sub>,x<sub>3</sub>,...,x<sub>n</sub>) = P(x<sub>1</sub>)P(x<sub>2</sub>|x<sub>1</sub>)P(x<sub>3</sub>|x<sub>1</sub>,x<sub>2</sub>)...P(x<sub>n</sub>|x<sub>1</sub>,...,x<sub>n-1</sub>)

5

The Chain Rule applied to compute joint probability of words in

 $P(w_1 w_2 ... w_n) = \prod P(w_i | w_1 w_2 ... w_{i-1})$ 

P("its water is so transparent") =

P(its) × P(water|its) × P(is|its water)

× P(so|its water is) × P(transparent|its water is so)

\_

How to estimate these probabilities

Could we just count and divide?

P(the lits water is so transparent that) = Count(its water is so transparent that the) Count(its water is so transparent that)

- No! Too many possible sentences!
- · We'll never see enough data for estimating these

8

8

Markov Assumption

• Simplifying assumption:

 $P(\text{the }|\text{ its water is so transparent that}) \approx P(\text{the }|\text{that})$ 

Or maybe

 $P(\text{the }|\text{ its water is so transparent that}) \approx P(\text{the }|\text{transparent that})$ 

9

Markov Assumption

$$P(w_1w_2...w_n) \approx \prod_i P(w_i \mid w_{i-k}...w_{i-1})$$

• In other words, we approximate each component in the product

$$P(w_i | w_1 w_2 ... w_{i-1}) \approx P(w_i | w_{i-k} ... w_{i-1})$$

20

10

Simplest case: Unigram model

 $P(w_1 w_2 \dots w_n) \approx \prod_i P(w_i)$ 

· Some automatically generated sentences from a unigram model

fifth, an, of, futures, the, an, incorporated, a, a, the, inflation, most, dollars, quarter, in, is, mass thrift, did, eighty, said, hard, 'm, july, bullish that, or, limited, the

11

Bigram model

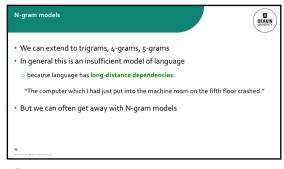

Condition on the previous word:

 $P(w_i | w_1 w_2 ... w_{i-1}) \approx P(w_i | w_{i-1})$ 

texaco, rose, one, in, this, issue, is, pursuing, growth, in, a, boiler, house, said, mr., gurrla, mexico, 's, motion, control, proposal, without, permission, from, five, hundred, fifty, five, yen outside, new, car, parking, lot, of, the, agreement, reached

this, would, be, a, record, november

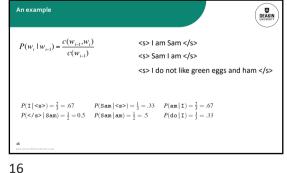

to an arrow orly 1977 to the following

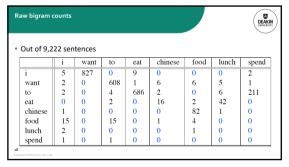

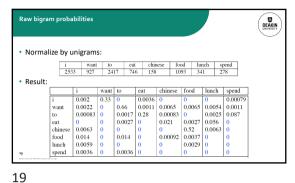

• The Maximum Likelihood Estimate  $P(w_i \mid w_{i-1}) = \frac{count(w_{i-1}, w_i)}{count(w_{i-1})}$   $P(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$ 

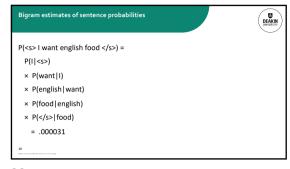

13 14 15

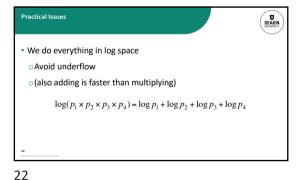

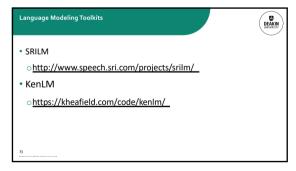

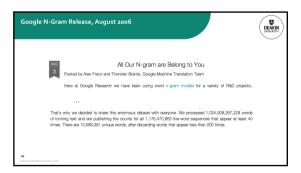

What kinds of knowledge?

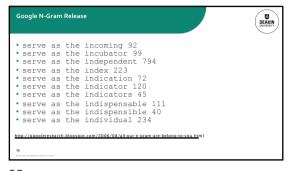

• P(english | want) = .0011
• P(chinese | want) = .0065
• P(to | want) = .66
• P(eat | to) = .28
• P(food | to) = 0
• P(want | spend) = 0
• P (i | <s>) = .25

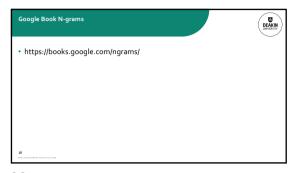

9 20 21

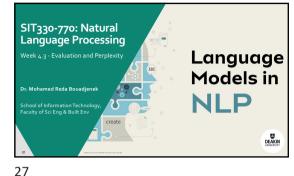

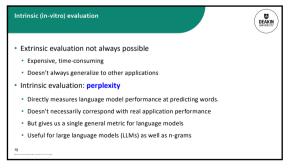

"Extrinsic (in-vivo) Evaluation"

To compare models A and B

 Put each model in a real task
 Machine Translation, speech recognition, etc.

Run the task, get a score for A and for B
 How many words translated correctly
 How many words transcribed correctly

Compare accuracy for A and B

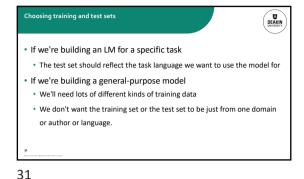

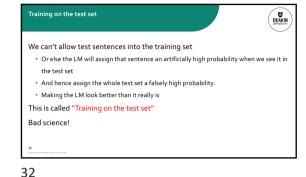

We train parameters of our model on a training set.

We test the model's performance on data we haven't seen.

A test set is an unseen dataset; different from training set.
Individual we want to measure generalization to unseen data
An evaluation metric (like perplexity) tells us how well our model does on the test set.

28 29 30

Dev sets DEAKIN UNIVERSITY • If we test on the test set many times we might implicitly tune to its characteristics • Noticing which changes make the model better. · So we run on the test set only once, or a few times · That means we need a third dataset: • A development test set or, devset. • We test our LM on the devset until the very end • And then test our LM on the test set once

33

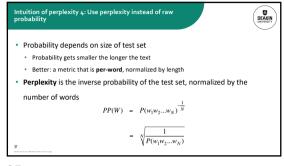

Intuition of perplexity as evaluation metric: How good is our language model? DEAKIN UNIVERSITY • Intuition: A good LM prefers "real" sentences Assign higher probability to "real" or "frequently observed" sentences Assigns lower probability to "word salad" or "rarely observed" sentences?

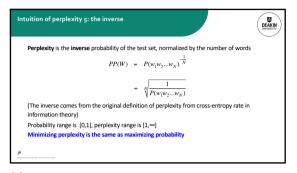

Intuition of perplexity 2: Predicting upcoming words DEAKIN UMAYERSITY The Shannon Game: How well can we predict the next word? Once upon a midnight 0.02 That is a picture of a \_\_\_\_ For breakfast I ate my usual \_\_\_\_ 1e-100 Unigrams are terrible at this game (Why?) A good LM is one that assigns a higher probability to the next word that actually occurs

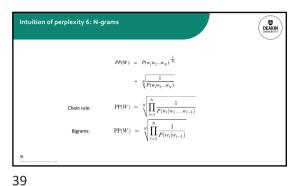

Intuition of perplexity 3: The best language model is one that best predicts the entire unseen test set DEAKIN UNIVERSITY • We said: a good LM is one that assigns a higher probability to the next word that actually occurs. · Let's generalize to all the words! · The best LM assigns high probability to the entire test set. When comparing two LMs, A and B We compute P<sub>A</sub>(test set) and P<sub>B</sub>(test set) • The better LM will give a higher probability to (=be less surprised by) the test set than the other LM.

35 36

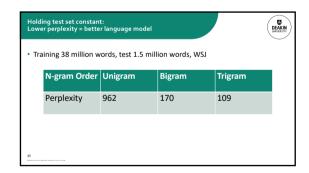

34

	Perplexity is also the weighted average branching factor of a language.
	Branching factor: number of possible next words that can follow any word
	Example: Deterministic language L = {red,blue, green}  Branching factor = 3 (any word can be followed by red, blue, green)
:	Now assume LM A where each word follows any other word with equal probability $\%$ Given a test set $T$ = "red red red blue"
	o Perplexity.(1) = Pu/red red red red blue) $^{1/5} = ((y_i)^5)^{-1/5} = (x_i)^{-1} = 3$ But now suppose red was very likely in training set, such that for LM B:
	o P(red) = .8 p(green) = .1 p(blue) = .1
•	We would expect the probability to be higher, and hence the perplexity to be smaller:  • Perplexity4(T) = Pulred red red blue)***

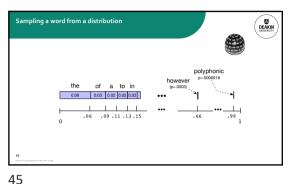

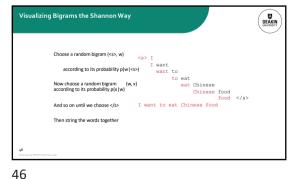

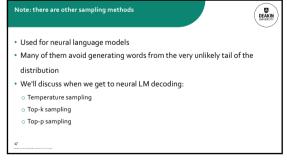

40 41 42

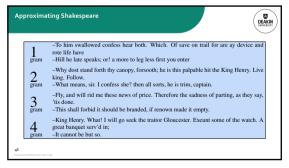

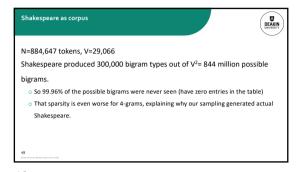

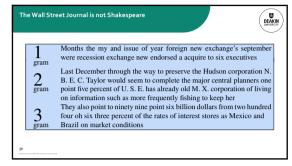

Can you guess the author? These 3-gram sentences are sampled from an LM trained on who?

1) They also point to ninety nine point six billion dollars from two hundred four oh six three percent of the rates of interest stores as Mexico and gram Brazil on market conditions 2) This shall forbid it should be branded, if renown made it empty.

3) "You are uniformly charming!" cried he, with a smile of associating and now and then I bowed and they perceived a chaise and four to wish for.

51

19

50

If task-specific, use a training corpus that has a similar genre to your task.
 If legal or medical, need lots of special-purpose documents
 Make sure to cover different kinds of dialects and speaker/authors.
 Example: African-American Vernacular English (AAVE)
 One of many varieties that can be used by African Americans and others
 Can include the auxiliary verb finna that marks immediate future tense:
 "My phone finna die"

N-grams only work well for word prediction if the test corpus looks like the training corpus

But even when we try to pick a good training corpus, the test set will surprise us!

We need to train robust models that generalize!

One kind of generalization: Zeros

Things that don't ever occur in the training set

But occur in the test set

• Training set:

... ate lunch

... ate lunch

... ate lunch

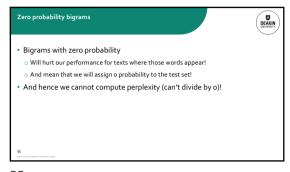

... ate breakfast

... ate the

P("breakfast" | ate) = 0

53 54

9

The intuition of smoothing (from Dan Klein)

• When we have sparse statistics:

Five | denied the)
3 allegations
2 reports
1 claims
7 total

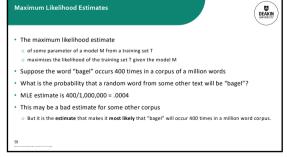

• Steal probability mass to generalize better

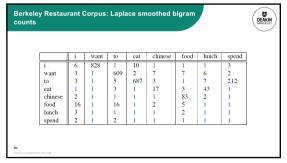

Five | denied the)
2.3 allegations
1.5 angerts
0.5 angerts
0.5 angerts
2 cotter
7 total

55 56 57

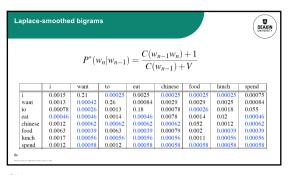

• Also called Laplace smoothing
• Pretend we saw each word one more time than we did
• Just add one to all the counts!

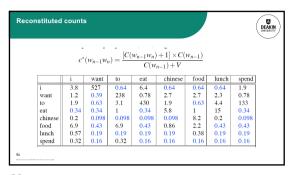

• MLE estimate:  $P_{MLE}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$ • Add-1 estimate:  $P_{Add-1}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i) + 1}{c(w_{i-1}) + V}$ 

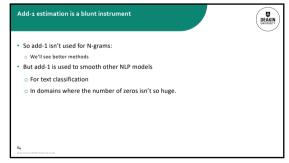

58 59 60

61 62 63

Sometimes it helps to use less context
Condition on less context for contexts you haven't learned much about

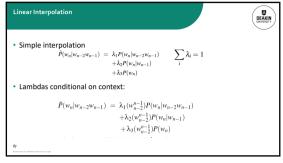

Backoff:
Use trigram if you have good evidence,
Otherwise bigram, otherwise unigram

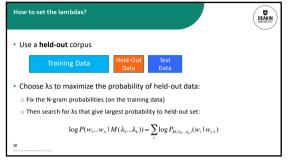

Interpolation:

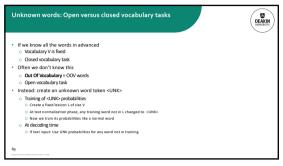

mix unigram, bigram, trigram

Interpolation works better

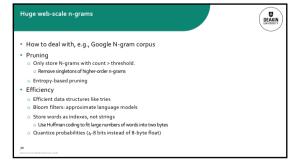

64 65 66

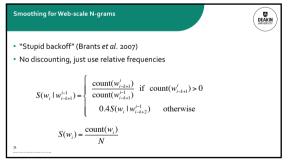

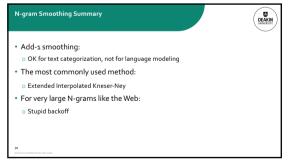

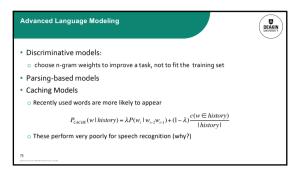

67 68 69

70

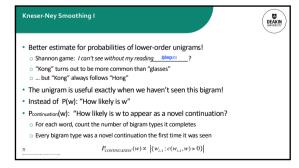

Absolute discounting: just subtract a little from each count DEAKIN UNIVERSITY Suppose we wanted to subtract a little from a count of 4 to save Bigram count in training Bigram count in heldout set probability mass for the zeros .0000270 How much to subtract ? 0.448 · Church and Gale (1991)'s clever idea 2.24 Divide up 22 million words of AP Newswire 3.23 o Training and held-out set 4.21 o for each bigram in the training set 5.23 o see the actual count in the held-out set! 6.21 It sure looks like c\* = (c - .75) 7.21 8.26

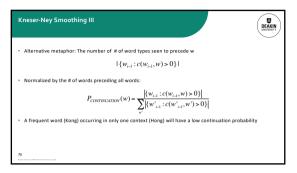

73 74 75

• Save ourselves some time and just subtract 0.75 (or some d)!  $P_{\text{Absolute Discounting}}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i) - d}{c(w_{i-1})} + \lambda(w_{i-1})P(w) \text{ unigram}$ • (Maybe keeping a couple extra values of d for counts 1 and 2)
• But should we really just use the regular unigram P(w)?

76

 $\begin{aligned} &\text{Kneser-Ney Smoothing II} \\ & \cdot \text{ How many times does w appear as a novel continuation:} \\ & P_{CONTINUATION}(w) \propto \left| \{w_{i,1} : c(w_{i,1}, w) > 0\} \right| \\ & \cdot \text{ Normalized by the total number of word bigram types} \\ & \left| \{(w_{j-1}, w_j) : c(w_{j-1}, w_j) > 0\} \right| \\ & P_{CONTINUATION}(w) = \frac{\left| \{w_{j-1} : C(w_{j-1}, w) > 0\} \right|}{\left| \{(w_{j-1}, w_j) : C(w_{j-1}, w_j) > 0\} \right|} \end{aligned}$ 

Kneser-Ney Smoothing IV  $P_{KN}(w_i \mid w_{i-1}) = \frac{\max(c(w_{i-1}, w_i) - d, 0)}{c(w_{i-1})} + \lambda(w_{i-1})P_{CONTINUATION}(w_i)$   $\lambda \text{ is a normalizing constant; the probability mass we've discounted}$   $\lambda(w_{i-1}) = \frac{d}{c(w_{i-1})} \Big| \{w: c(w_{i-1}, w) > 0\} \Big|$  The normalized discount is the normalized discount in the normalized discount is a of times we applied normalized discount in the normalized discount in the normalized discount is a full times we applied normalized discount in the normalized disco

 $R_{KN}(w_i \mid w_{i-n+1}^{i-1}) = \frac{\max(c_{KN}(w_{i-n+1}^i) - d, 0)}{c_{KN}(w_{i-n+1}^i)} + \lambda(w_{i-n+1}^{i-1}) P_{KN}(w_i \mid w_{i-n+2}^{i-1})$   $c_{KN}(\bullet) = \begin{cases} count(\bullet) & \text{for the highest order} \\ continuation count(\bullet) & \text{for lower order} \end{cases}$  Continuation count = Number of unique single word contexts for  $\bullet$
